Who’s that Knocking on My Tree??

In the winter when the leaves are off the trees it is easier to see who is visiting our backyards and feeders. One family in particular is easier to see now since they are pretty secretive during the breeding season. We generally hear them before we see because they are usually banging on something. Here is some basic information about these frequent visitors to our suet feeders adapted from an article by Chuck Fergus.

A drum roll at dawn, a bird in undulating flight through the forest, wood chips littering the ground at the base of a tree - all these signal the presence of a woodpecker, a highly specialized and important member of nature’s highly complex world.

Woodpeckers have been around for a long time: their fossil remains date back 25 million years to the Lower Miocene, and they’re widely distributed, with 45 species in the U.S. and more than 200 worldwide. Seven species either live year-round in the Charlotte/Gastonia area or visit in winter. The common flicker (yellow-shafted phase), pileated woodpecker, red-bellied woodpecker, red-headed woodpecker, hairy woodpecker, and downy woodpecker are residents. The yellow-bellied sapsucker is a winter visitor.

The woodpecker family, Picidae, fills a unique niche in the food-gathering chain. Woodpeckers drill into trees to uncover insect food, to create nesting shelters and...
**Downy Woodpecker**

*Length:* 5-6 inches; *wingspread:* 11 1/2 inches. The downy - most common of the eastern woodpeckers - resembles a small hairy woodpecker, with a similar white back stripe and white breast. The male has a red patch on the back of his head, similar to that on the hairy. Bill length of the downy is less than the width of its head, while that of the hairy is equal to or greater than the width of its head. The downy’s outer tail feathers are barred with black (in the hairy woodpecker, these are solid white). *Food:* wood-boring larvae, moths, beetles, ants, aphids, spiders, poison ivy and dogwood fruits, berries, corn, apples, and acorns. Habitat: open forests of mixed growth, orchards, suburbs, and parks. Nests are usually dug in rotting wood, 3-50 feet above the ground and often on the underside of an exposed limb. *Eggs:* 3-6, usually four or five, incubated 12 days. The downy woodpecker is a common resident in all seasons. *Calls:* a soft pik and a rattling sound.

**Yellow-Bellied Sapsucker**

*Length:* 7-8 inches; *wingspread:* 14 inches. Plumage varies within the species, but the narrow longitudinal wing stripes -- visible when the bird is at rest -- and the finely mottled back are good field marks. (The back coloration blends well with tree bark.) The belly is tinged yellow, and the head is red, black and white.

Sapsuckers drill parallel rows of holes in live trees (up to 30 holes per day) and return later to drink sap and catch small insects attracted to the sweet liquid. The bushy tongue of a sapsucker effectively soaks up sap. Other foods include beetles, ants, caterpillars, insect eggs, spiders; the cambium (layer beneath the bark) of maple, aspen, birch, fir, hickory, beech, pine, oak and other trees; fruits and seeds.

Sapsuckers inhabit forests, orchards, and woodlots. *Nest:* a gourd-shaped cavity excavated 8-40 feet up a tree; aspen and other trees afflicted with tinder fungus are often chosen as nest sites, because the fungus creates a soft center that is easily dug out. *Eggs:* 4-7, usually five or six, with a 12- to 13-day incubation period. The sapsucker is the most migratory of our woodpeckers. The sapsucker is a winter visitor to the area. *Call:* a jay-like mewing note. Also, sapsuckers tap in a distinctive rhythm, two or three series per minute; they do not drum.

**Hairy Woodpecker**

*Length:* 8-9 inches; *wingspread:* 15 inches. This woodpecker has a vertical white stripe down the center of its back, black wings stippled with white on the upper sides, white feathers forming the outer edge of the tail, and white breast. Sexes are similar, but the female lacks the male’s small red patch on the back of the head. Larger size and a proportionately longer bill distinguish it from the downy woodpecker. *Food:* The hairy eats beetle larvae, ants, caterpillars, adult beetles, spiders, etc.; also seeds and fruits. Primary habitat is forest land and wooded swamps. *Nest:* 5-30 feet up; the male may also dig a roosting cavity. *Eggs:* 3-6, commonly four, with a 12-day incubation period.

**Red-Bellied Woodpecker**

*Length:* 8-9 inches; *wingspread:* 17 inches. This woodpecker has a “ladder back” (a pattern of black and white bands like a ladder), red cap and back of neck, and a breast tinged a very light red. The female’s crown is gray, the immature’s entire head is brown, and the male’s crown and neck are red. *Food:* acorns, beechnuts, hickory nuts, grapes, and corn; mulberry, poison ivy, and dogwood fruits; beetles, wood-boring larvae, and ants. Red-bellied woodpeckers inhabit coniferous and deciduous forests, woodlots, orchards, and yards. *Nest:* 5-70 (usually less than 40) feet up a tree or utility pole. *Eggs:* 3-8, commonly four or five, with two weeks incubation. *Call:* a low, hoarse chuh chuh; also a rattling noise.
Northern Flicker

Length: 8-10 inches; wingspread: up to 20 inches (about the size of a blue jay). Flickers, also known as yellowhammers, have brown backs, no white on the wings, a prominent black band high on the breast, and bright red on the nape of the neck. The male has a black “mustache” mark extending from the bill back onto the throat. In flight, the white rump patch and yellow underwings show up well. Flickers are often seen on the ground or on sidewalks eating ants, a preferred food. Their saliva neutralizes the formic acid which ants contain. They also eat beetles, grasshoppers, crickets and other insects. In fall and winter, they eat poison ivy fruits, berries, corn, and sumac seeds. Favored habitat is woodland, orchards, woodlots, and yards. Nest: a hole opening into a cavity, 2-60 feet up a tree. The cavity takes up to two weeks to build. Eggs: 3-10, usually 6-8, with an 11- to 12-day incubation period. Starlings may drive flickers out of their newly-dug cavities. Call: a loud flick or flicker, 2-7 times per minute; also a shrill, descending kee-oo.

Pileated Woodpecker

Length: 12-17 inches; wingspread: up to 27 inches; crow-size but with a long, slender neck. The largest American woodpecker next to the nearly extinct and closely related ivorybill. Also called the Indian hen and log cock, a pileated woodpecker has a solid black back and a conspicuous red crest for which it is named (from the Latin word for cap, pilleus). The female is similar to the male but does not have red cheek patches and has less red in the crest. Flight is strong, with irregular wing flapping accompanied by white flashing of wing undersurfaces. Foods include ants, beetles, wood-boring larvae and wild fruits. Pileated woodpeckers inhabit mature coniferous and deciduous forests, valley woodlots and remote mountain territory. Nest: a new hole excavated each year in the same nest area, 15-70 feet up (average 45 feet). The entrance hole is usually oval, and the cavity is 10-24 inches deep. Eggs: 3-4, incubated 18 days. These birds are uncommon residents in all seasons.

A pileated’s powerful beak can break loose fist-sized chunks of wood; the bird twists its head and beak as it strikes to add leverage. Pileateds cut large rectangular holes in dead trees, spars, live conifers, and utility poles. They drum loudly and rapidly, then more slowly, trailing off softly at the end. Call: wick-uh wick-uh wick-uh, in a series; also kuk, kuk, kuk, kuk-kuk-kuk.

Red-Headed Woodpecker

Length: 8-9 inches; wingspread: 18 inches. The head of an adult of this species is scarlet, and that of a juvenile, brown. Body plumage is black and white, with a large white wing area visible when the bird flies. Like the flicker, the red-headed woodpecker does a lot of feeding on the ground. It eats beetles, ants, grasshoppers, caterpillars, other insects, acorns, corn, wild fruits, apples. Redheads store acorns in tree cavities during winter and defend these food caches against squirrels and other birds. Habitat is open forestland, farm woodlots, towns and parks. This bird often perches in the open. Nest: 8-80 feet up, often in an oak and occasionally in a fencepost. Starling competition for nesting sites may be reducing this species’ numbers. Eggs: 4-7, usually five, with a 14-day incubation period. In spring, the redhead is an uncommon migrant in late April and early May; in summer, a breeding resident; in fall, an uncommon migrant from September to early November; and a winter resident. Call: a raucous kwrrk.
